

Volta-HYCOS PROJECT

TRAINING SESSION ON RATING CURVES :

Case study

Accra, 23rd – 27th April 2007

CASE STUDY

RATING CURVE OF THE SENEGAL RIVER AT GOUINA – UPSTREAM STATION

The rating curve of the Senegal River at Gouina-upstream station is of a single value stage/discharge relationship type, steady and without any anomaly. The station is located upstream of a fall of about 10 meters, and therefore has a very efficient downstream control section.

Numerous flow measurements have been carried out for mean water levels, for which the water surface slope has been measured. The rating curve is well defined for mean water levels, but the extension from a flow of $2\,500\text{ m}^3\cdot\text{s}^{-1}$ to $7\,000\text{ m}^3\cdot\text{s}^{-1}$ is quite difficult.

I LOCATION OF THE STATION

Gouina station is located in the upper part of the Senegal River basin at about 50 km from Kayes city, an important regional capital in the Republic of Mali.

The coordinates of the station are: 14°00N & 11°06W

II CHARACTERISTICS OF THE STATION

See figures A2.1, A2.2 & A2.3

2.1 The first staff gauge was installed in 1925 by UHEA Company in charge of the hydro-power dam project at the level of Gouina falls (height about 10 meters). The catchment area is of 128 600 km².

2.2 Six different sections for the staff gauges have been used from 1925 to 1979 to monitor the water levels of the river.

The cross section of the upstream station, for which the rating curve is studied in this example, is of a quite complex shape (see fig. A2.3) with a double central canal, a maximum depth of more than 20 meters for high water levels and a channel width of about 300 meters. The river bed is rocky and perfectly steady.

2.3 The cross section levelling carried out by the UHEA Company was in 4th June 1951 and allowed the definition, with a good accuracy, of the relationships W(h) (Wetted Area) and R(h) (Hydraulic radius), h being the water level at the upstream water level recorder. Table A2.1 shows the list of the 27 levelling points and all the geometric parameters of the cross section.

Figure A2.6 shows the shape of the W(h) & R(h) curves. To facilitate the extension calculations these two curves are given by the formula below:

- Wetted area : $W = 0.000259 h^2 + 2.2993 h + 1261$
o for $0 < h < 692$ (max water level)

The error in W is less than 0.1% for the whole range

- Hydraulic radius : $R = 0.007982 h + 5.42$ for $0 < h < 550$
 $R = -0.0000207 h^2 + 0.008577 h + 9.81$ for $550 < h < 700$

The error in R is less than 0.3% for both equations.

Remark: We have drawn on figures A2.4 & A2.5 the variations in wetted area and in hydraulic radius with the water level for the whole section. As the W curve is very regular, it is very different for the R curve.

2.4 The gauging section for the mean and high water levels is located 1 040 m upstream and at about 3 km upstream of the falls. The cross section profile is more regular and the section is wider at the gauging section(see fig. A2. 3).

III HYDROMETRIC EQUIPMENT

3.1 Four staff gauges have been installed at Gouina station, on the left bank of the river between 1925 and 1929. These staff gauges rank from upstream to downstream are:

- Staff gauge N°1 installed in 1925 just upstream of the falls and made of a leaning rail graduated from 0 to 5 meters;
- Staff gauge N°2 equipped the first reach at the foot of the falls. It is a vertical rail of 8 meters, fixed on a concrete pile against the rocky bank of the river;
- Staff gauge N°3 is located at the beginning of the second reach downstream the falls it is also a vertical rail of 8 meters;
- Staff gauge N°3 equipped the third reach. It is located 900 meters downstream the previous one in the area planed by UHEA for the tail water of the hydropower plan of Gouina. It is a vertical rail of 9 meters.

3.2 UHEA has completed this equipment with two water level recorders in 1950:

- The first installation is called Gouina-upstream (Bär trade mark, mensual type) and is located 2 km upstream of the falls. Its gauge Zero level is at an altitude of 63.35 meters MEFS (Mission d'Etudes du Fleuve Senegal);
- The other installation is called Gouina-downstream (same trade mark) and is located on the right bank at about 400 meters downstream of the staff gauge N°4. Its gauge Zero level is at an altitude of 48.09 meters MEFS.

3.3 From 1953 the MAS (Mission d'Aménagement du Senegal) neglected the four staff gauges of UHEA but monitored the two water level recorders and added to them auxiliary staff gauges.

3.4 This historical summary of the Gouina station historical gives an idea of the work that has been done to ensure a homogeneous water level time series: with six different sections the problem must be complex.

IV WATER LEVEL SERIES

4.1 The four old staff gauges have been monitored from 1925 to 1950: the staff gauge N°1 from 1929 to 1942, and the three others from 1936 to 1942.

The correspondence graphs, built in plotting the water levels at the staff gauges N°1, N°2, N°4, against the water levels at the staff gauge N°3, show a high scattering of the results which gave evidence of the wrong readings. As the readings have also a lot of gaps it has not be possible to use them. So, despite the very nice and useful installations from a building point of view as two staff gauges are always in a very good condition today, the readings between 1925 and 1950 are useless.

This situation is due to the lack of staff gauges maintenance which were either badly graduated or unreadable and to the fact that the gauge readers were inefficient. Nevertheless, we have kept the maximum water levels data observed during this period. For Gouina-

upstream the maximum observed water level between 1929 and 1942 was 600 cm (it occurred in 1935).

4.2 From June 1950 to October 1952, UHEA took advantage of the whole set of staff gauges of the 1st, 2nd and 3rd reaches and of both the upstream and downstream water level recorders. The only missing information was the record of the peak flood in 1950.

4.3 From 1953 to 1956 the staff gauges at Gouina station were no more observed and the monitoring of the water levels is hazardous. Despite this situation, we have corrected the records and filled the gaps for the missing or bad data.

4.4 Data are then completed from 1953 to 1955. For 1954 two months of data are missing (September and October). Since 1956 we have completed and accurate readings for the 2nd reach staff gauges, installed by the M.A.S. After two years of good monitoring (1956 & 1957), the water level recorders were no more monitored.

4.5 During the period for which records are available in the ORSTOM files, i.e. from June 1st 1955 to December 31st 1979, the maximum water levels recorded at Gouina-upstream are:

- 692 cm on the 24/08/1958 for the maximum (978 cm at the 2nd reach staff gauge)
- 626 cm on the 04/06/1964
- 613 cm on the 23/08/1964
- The minimum water level of 25 cm occurred in 1976 (no date).

V GAUGING & CALIBRATION

5.1 Sixty one flow measurements have been carried out by UHEA for water levels recorded at the upstream water level recorder ranging from 0.68 m to 4.21 m (discharge from $6.5 \text{ m}^3 \cdot \text{s}^{-1}$ to $2\,300 \text{ m}^3 \cdot \text{s}^{-1}$).

Table A2.2 shows chronological series of the flow measurements and table A2.3 the ranking list of these gaugings.

For the gauging in mean and high water levels, the water surface profiles were levelled each time with respect to the benchmark N°11 (alt. 70.84 m MEFS); So, are known the difference in level between the gauging point and the recorder sections (distance 1 040 m). For the low water levels, gaugings were carried out at Dipari village (6 km upstream of Galougo). A control measurement has been carried out at this section by ORSTOM in 1965.

5.2 The 61 gaugings carried out by UHEA were undertaken between October 1950 and June 1952. The ORSTOM gauging carried out in February 1965 is of a high importance as it is the single one during the period of records. It is a chance that the calibration is steady and that the upstream and downstream staff gauges relationship is well known.

On the other hand, the two gauging carried out on 3rd & 4th of October 1951 are not usable due to cable breaking over the cross section. Despite this, the two gauging are very important as the water surface slope was measured.

The results of the discharge measurements are very good and gave an excellent rating curve between the stage 0.65 and 4.20 m (6 to $2\,300 \text{ m}^3 \cdot \text{s}^{-1}$). The curve is very regular (Fig. A2. 7),

the gaugings are enough and the good distribution of the gaugings enables to avoid any uncertainty in the drawing, except for discharges less than $100 \text{ m}^3 \cdot \text{s}^{-1}$. In view of the large cross section at Gouina-upstream, it is observed that the station is not very sensitive.

The single value stage/discharge relationship type at this station is confirmed by the graph as it was expected due to the location upstream of the falls.

The mean deviation between the measured discharges and the calculated one is of 3.3% for the 60 gaugings carried out by UHEA & IRD and 2.3 % for the gauging out of the stage 1.50 m. This shows the excellent quality of the gauging carried out by UHEA.

If the water level range were just a little bit more than the maximum gauging the extension of the rating curve of Gouina upstream would be easy, but the curve has to be extrapolated to the level 6.92 m (i.e. an additional 2.70 m).

VI RATING CURVE EXTENSION

6.1 Remark

A gauging carried out by a Russian team in 1965 doesn't appear in the list, as it was known only after this study. So, the value was not used in establishing the rating curve but for validation.

Taking into account the three usual methods for rating curve extension, it will be useful to check the limits of use for each one and to make his own judgment if the constraints are respected or not.

6.2 Logarithmic method

Constraint 1 (Single value stage/discharge relationship of exponential type), 3 (Regular shape cross section), and 4 (downstream hydraulic control) are well respected. On the other hand, the second constraint (numerous gauging up to a sufficient water level) is not well respected, despite the fact that the plotting of the gauging shows a good alignment of the points (Fig. A2.8) and allows an attractive but daring extension. The discharge for the maximum water level (692 cm) can be read directly on the graph: $9400 \text{ m}^3 \cdot \text{s}^{-1}$.

6.3 Steven's method

The use constraints are the same as for the previous method and, as for this one the gauging are not enough to well define the curve of discharges. Figure A2.9 shows this deficiency better than in the figure A2.8, maybe due to logarithmic coordinates? The extension of the discharge curve may or may not give good results :

- The extension has to be made according to the line (1), fitted with the gauging points between $1\ 000$ & $2\ 300 \text{ m}^3 \cdot \text{s}^{-1}$, the result for the maximum discharge is $6\ 150 \text{ m}^3 \cdot \text{s}^{-1}$ for the stage 692cm;
- The Stevens method doesn't allow the extension following the curve (2) which brings to the result of the log. Method;

- We will justify below the extension following the curve (3), drawing which cannot be “guessed” a priori.

6.4 Slope - Area method

Even if the wetted area is fully defined till the maximum level, the extension of the relationship $U(h)$ (U = mean velocity) is not possible (see fig; A2.10). So, it is necessary to use the Strickler’s formula, accordingly we known the value of the surface water slope for all complete gauging and also for the two incomplete one carried out for stages 489 & 557 cm.

The two parameters that we have to calculate are the roughness coefficient (K) and the water surface slope. Figure A2.11 shows the distribution of the K coefficient for all the gauging. We have retained the value of $K = 19$ which correspond to the two maximum gauging stages. It will be possible also to select the value $K = 1$ which correspond to the median value, but it seems that K is not yet stabilized for the stage 420 cm.

On figure A2. 12 the relationship $J(h)$ is represented, the two values of the water surface slope measured for the stages 489 & 557 are of a high interest to guide the extension of the curve to the stage 692 cm. The extension is made quasi-linear as we don’t have any more information.

The extension consists in the estimation of the K value and the drawing of the $J(h)$ curve to the 692 range.

With $K = 19$ and the value of the surface water slope read on the figure A2. 12, we have to calculate the discharges for the maximum stages by using the Strickler formula:

| H cm | S m ² | R m | J cm/km | $KJ^{1/2}$ | U m/s | Q calculated m ³ /s | Q tabulated m ³ /s | Deviation % |
|---------|---------------------|--------|------------|------------|----------|-----------------------------------|----------------------------------|----------------|
| 489 | 2447 | 9.32 | 30.19 | 0.330 | 1.662 | 3580 | 3510 | + 2.0 |
| 557 | 2622 | 9.87 | 43.27 | 0.395 | 1.819 | 4770 | 4770 | 0 |
| 613 | 2591 | 10.27 | 56.00 | 0.450 | 2.124 | 5880 | 5850 | + 0.6 |
| 626 | 2802 | 10.34 | 58.00 | 0.458 | 2.172 | 6085 | 6100 | - 0.2 |
| 692 | 2976 | 10.61 | 73.50 | 0.515 | 2.487 | 7400 | 7400 | 0 |

The rating curve is shown on figure A2. 14.

Remark: The shape of the $U(h)$ & $KJ^{1/2}$ curves (fig. A2.10 & A2.13) are a little bit strange, in fact, this is regular as the K value is not yet stabilized and the value of J increased more slowly.

VII CONCLUSION

The case study of the rating curve calibration for the Gouina upstream station on the Senegal River shows that it is very important to check the three methods for the extension of the rating curve, the difference in the results obtain by the logarithmic and Stevens methods should alert the operator. The water surface slope variation study in respect with the elevation of the water level is the single method to solve correctly this problem.

This also shows the importance of carrying out levelling on each station as well as cross section and longitudinal profiles.
